1 Equational Unification

In the following let E be a set of identities of the form $\{e_1 \approx f_1, \dots, e_n \approx f_n\}$. Furthermore let Sig(E) denote the set of all function symbols occurring in E. Let Σ be a finite set of function symbols and a superset of Sig(E).

Definition 1.1. An *E*-unification Problem over Σ is a finite set *S* of the form $S = \left\{ s_1 \stackrel{?}{\approx}_E t_1, \dots, s_n \stackrel{?}{\approx}_E t_n \right\}$ with $s_1, \dots, s_n, t_1, \dots, t_n \in T(\Sigma, V)$, *V* being a countable set of Variables.

A substitution σ is an *E*-unifier of *S* iff $\sigma(s_i) \approx_E \sigma(t_i)$ for all $1 \leq i \leq n$. The set of all *E*-unifiers of *S* is denoted by $\mathcal{U}_E(S)$. *S* is *E*-unifiable iff $\mathcal{U}_E(S) \neq \emptyset$.

Definition 1.2. Let S be an E-unification problem over Σ .

- S is an elementary E-unification problem iff $Sig(E) = \Sigma$.
- S is an E-unification problem with constants iff $\Sigma Sig(E) \subseteq \Sigma^{(0)}$ and $Sig(E) \subset \Sigma$
- S is an **general** E-unification problem iff $\Sigma Sig(E)$ contains an at least unary function symbol.

One most general unifier does not always suffice to represent $\mathcal{U}_E(S)$. In this case we need a minimal complete set of unifiers but to define this set we first need an order on substitutions.

Definition 1.3. Let X be a set of variables. A substitution σ is **more general** modulo \approx_E than a substitution σ' on X iff there is a substitution δ such that $\delta(\sigma(x)) \approx_E \sigma'(x)$ for all $x \in X$. We denote this by $\sigma \lesssim_E^X \sigma'$.

 \lesssim^X_E is a is a quasi order since it obviously is reflexive and transitive. But why do we only demand equality modulo \approx_E on X and not on all Variables like we did in syntactic unification? Note that by the restriction to Variables in Xmore substitutions are comparable with respect to \lesssim_E^X since we do not demand equality modulo \approx_E on all Variables. Lets denote the Variables occurring in an E-unification problem S by Var(S). It is easy to see that if X = Var(S), σ' is an E-unifier of S and $\sigma \lesssim_E^X \sigma'$ then σ is also an E-unifier of S. This only shows that restriction to X does not do any damage but the reason it is useful is that there are E-unification problems S for which any minimal complete set of Eunifiers has to contain Variables not occurring in S. Lets consider a small example, let $\sigma := \{x \mapsto f(y)\}$ be in \mathcal{M} a minimal complete set of E-unifiers of S with $\mathcal{V}ar(S) = \{x\}$ and $\{a \approx x\} \notin E$. Clearly $\sigma' := \{x \mapsto f(a)\}$ is also an E-unifier of S but σ and σ' are incomparable w.r.t. $\lesssim_E^{\{x,y\}}$. The substitution $\delta := \{y \mapsto a\}$ does not work here since $\delta(\sigma(y)) = a \not\approx_E y = \sigma'(y)$ which means there has to be another unifier σ'' in \mathcal{M} with $\sigma'' \lesssim_E^{\{x,y\}} \sigma$. But if we restrict Xto $\{x\}$ we only need that $\delta(\sigma(x)) = f(a) \approx_E f(a) = \sigma'(x)$ so $\sigma \lesssim_E^{\{x\}} \sigma'$ holds. We see that minimal complete sets of E-unifiers can become unnecessary large if we consider all Variables. Since we have talked about these sets a lot lets define them formally.

Definition 1.4. Let S be an E-unification problem over Σ and let $X := \mathcal{V}ar(S)$. A **complete set of** E-**unifiers** of S is a set of substitutions \mathcal{C} that satisfies the following properties.

- each $\sigma \in \mathcal{C}$ is an E-unifier of S
- for all $\theta \in \mathcal{U}_E(S)$ there exists a $\sigma \in \mathcal{C}$ such that $\sigma \lesssim_E^X \theta$

A minimal complete set of E-unifiers is a complete set of E-unifiers \mathcal{M} that satisfies the additional property

• for all $\sigma, \sigma' \in \mathcal{M}, \ \sigma \lesssim_E^X \sigma'$ implies $\sigma = \sigma'$.

The substitution σ is a **most general** E-unifier (mgu) of S iff $\{\sigma\}$ is a minimal complete set of E-unifiers of S.
